July 4th, 2018

## 1. Preliminary

- Cayley graph  $Cay(G, S)$  and the neighbourhood of a vertex
- Group algebra  $\mathbb{F}[G]$  and the action by multiplication
- A bridge between  $Cay(G, S)$  and  $\mathbb{F}[G]$
- The bridge between the Star graph  $S_n$  and the Jucys-Murphy element  $J_n$
- A result by Jucys on eigenvectors of  $J_n$
- Permutation module  $M^\lambda$  and Specht module  $S^\lambda$
- An embedding of the permutation module  $M^\lambda$  into  $\mathbb{C}[Sym_n]$
- Standard basis of the Specht module and eigenvectors of  $J_n$  given by a polytabloid

## 2. Our results

- A family of eigenfunctions of the Star graph  $S_n$  called  $PI$ -eigenfunctions
- A connection between eigenfunctions given by a polytabloid and  $PI$ -eigenfunctions

# Cayley graph and the neighbourhood of a vertex

Let  $G$  be a group. For a non-empty inverse-closed identity-free subset  $S$  in  $G$ , define the **Cayley graph**  $\text{Cay}(G, S)$  with the vertex set  $G$  and two vertices  $x, y$  being adjacent whenever there is an element  $s \in S$  such that  $y = sx$  holds.

Given a vertex  $x$  in  $\text{Cay}(G, S)$ , the equality

$$N(x) = Sx$$

holds, where  $N(x)$  is the neighbourhood of  $x$ .

# Group algebra $\mathbb{F}[G]$ and the action by multiplication

Take a field  $\mathbb{F}$ , a group  $G$  and the group algebra  $\mathbb{F}[G]$ .

For a subset  $S$  in  $G$ , consider the element  $\overline{S} \in \mathbb{F}[G]$  given by

$$\overline{S} = \sum_{s \in S} s.$$

Left multiplication of elements from  $\mathbb{F}[G]$  by  $\overline{S}$  is a linear transformation of  $\mathbb{F}[G]$ .

The transformation matrix of this linear transformation coincides with the adjacency matrix of  $\text{Cay}(G, S)$ , which gives a bridge between spectral properties of Cayley graphs and the representation theory.

# Eigenfunction of a graph

Let  $\Gamma = (V, E)$  be a regular graph.

A function  $f : V \rightarrow \mathbb{R}$  is called an **eigenfunction** of the graph  $\Gamma$  corresponding to an eigenvalue  $\theta$  if  $f \not\equiv 0$  and for any vertex  $x$  the local condition

$$\theta \cdot f(x) = \sum_{y \in N(x)} f(y)$$

holds, where  $N(x)$  is the set of neighbours of the vertex  $x$ .

We put

- $G := Sym_n$
- $\mathbb{F} := \mathbb{C}$
- $S := \{(i \ n) \mid i = 1, \dots, n-1\}$
- The graph  $S_n := Cay(G, S)$  is called the **Star graph**
- The element  $J_n := (1 \ n) + \dots + (n-1 \ n)$  from  $\mathbb{C}[Sym_n]$  is called the **Jucys-Murphy element**

# Partitions and Ferrers diagrams

Take the partition  $\lambda = (4, 2, 1)$  of the number  $n = 7$ . Then the corresponding Ferrers diagram is as follows:

A tableau  $t$  is **standard** if the rows and columns of  $t$  are increasing sequences.

# Standard Young tableaux of shape $\lambda = (4, 2, 1)$

$$c(n) = 3$$

<table><tr><td>1</td><td>2</td><td>6</td><td>7</td></tr><tr><td>3</td><td>5</td><td></td><td></td></tr><tr><td>4</td><td></td><td></td><td></td></tr></table>	1	2	6	7	3	5			4				,	<table><tr><td>1</td><td>2</td><td>5</td><td>7</td></tr><tr><td>3</td><td>6</td><td></td><td></td></tr><tr><td>4</td><td></td><td></td><td></td></tr></table>	1	2	5	7	3	6			4				,	<table><tr><td>1</td><td>2</td><td>6</td><td>7</td></tr><tr><td>3</td><td>4</td><td></td><td></td></tr><tr><td>5</td><td></td><td></td><td></td></tr></table>	1	2	6	7	3	4			5				,	<table><tr><td>1</td><td>2</td><td>4</td><td>7</td></tr><tr><td>3</td><td>6</td><td></td><td></td></tr><tr><td>5</td><td></td><td></td><td></td></tr></table>	1	2	4	7	3	6			5				,	<table><tr><td>1</td><td>2</td><td>5</td><td>7</td></tr><tr><td>3</td><td>4</td><td></td><td></td></tr><tr><td>6</td><td></td><td></td><td></td></tr></table>	1	2	5	7	3	4			6				,	<table><tr><td>1</td><td>2</td><td>4</td><td>7</td></tr><tr><td>3</td><td>5</td><td></td><td></td></tr><tr><td>6</td><td></td><td></td><td></td></tr></table>	1	2	4	7	3	5			6				,

# Decomposition of the regular representation of $Sym_n$

The regular representation of  $Sym_n$  is decomposed into irreducible submodules as follows

$$\mathbb{C}[Sym_n] = \bigoplus_{\lambda \in \mathcal{P}(n)} m_\lambda V_\lambda,$$

where  $\mathcal{P}(n)$  the set of partitions of  $n$  and  $m_\lambda = \dim V_\lambda$ .

## Theorem (Jucys, 1974)

*Let  $\lambda \in \mathcal{P}(n)$ . Then there exists a basis  $\{v_t\}$  of the irreducible module  $V_\lambda$ , indexed by standard Young tableaux  $t$  of shape  $\lambda$  such that for all  $i \in \{2, \dots, n\}$ , the equality*

$$J_i v_t = c_t(i) v_t$$

*holds.*

If  $i = n$ , the theorem says that there exists a basis of an irreducible module  $V_\lambda$  consisting of eigenvectors of  $J_n$ .

Moreover, the number of eigenvectors corresponding to the same eigenvalue is given by the number of standard Young tableaux of the shape  $\lambda$  with the same value  $c(n)$ .

$$\lambda = (4, 2, 1)$$

The irreducible module  $V_\lambda$  has dimension 24.

The basis contains

- 12 eigenvectors of  $J_7$  with eigenvalue 3,
- 6 eigenvectors with eigenvalue 0,
- 6 eigenvectors with eigenvalue  $-2$ .

# The spectrum of the Star graph $S_n$

## Corollary

*For any  $n \geq 4$ , the spectrum of the Star graph  $S_n$  consists of integers  $-(n-1), \dots, n-1$ , and the multiplicity of an eigenvalue  $\theta$  is given by the formula*

$$\text{mul}(\theta) = \sum_{\lambda \in \mathcal{P}(n)} m_{\lambda} \cdot C_{\lambda}(k),$$

*where  $m_{\lambda}$  is the number of standard Young tableaux of shape  $\lambda$  and  $C_{\lambda}(k)$  is the number of standard Young tableaux of shape  $\lambda$  with  $c(n) = k$ .*

Let  $\lambda$  be a shape with  $n$  cells.

For a tableau  $t$  of shape  $\lambda$ , the  **$\lambda$ -tabloid**  $\{t\}$  is the set of all tableaux of shape  $\lambda$  that can be obtained from  $t$  by permutations of elements in rows.

Let  $M^\lambda = \mathbb{C}\{\{t_1\}, \dots, \{t_k\}\}$  be the permutation module corresponding to  $\lambda$ , where  $\{t_1\}, \dots, \{t_k\}$  is a complete list of  $\lambda$ -tabloids.

Further, we consider the action of the group algebra  $\mathbb{C}[Sym_n]$  on  $M^\lambda$ .

Let  $t$  be a tableau of shape  $\lambda$ .

Let  $C_t$  be the column stabilizer of  $C_t$ .

Put

$$\mathbf{e}_t := \sum_{\pi \in C_t} \operatorname{sgn}(\pi) \{\pi(t)\}.$$

The element  $\mathbf{e}_t \in M^\lambda$  is called the **polytabloid** given by the tableau  $t$ .

# Specht module $S^\lambda$ and its standard basis

Given a partition  $\lambda$ , the corresponding **Specht module**  $S^\lambda$ , is the submodule of  $M^\lambda$  spanned by all polytabloids  $\mathbf{e}_t$ , where  $t$  is of shape  $\lambda$ .

A polytabloid  $\mathbf{e}_t$  is **standard** if the tableau  $t$  is standard.

The set of standard polytabloids

$$\{\mathbf{e}_t \mid t \text{ is a standard tableau of shape } \lambda\}$$

forms a basis of the Specht module  $S^\lambda$ .

# An embedding $\phi$ of $M^\lambda$ into $\mathbb{C}[Sym_n]$

Let  $id_\lambda$  be the standard tableau of shape  $\lambda$  whose rows consist of the consecutive elements.

Let  $T_\lambda$  be the set of all tableaux of shape  $\lambda$ . For any tableau  $t \in T_\lambda$ , denote by  $\tau_t$  the permutation defined by the equation

$$\tau_t(t) = id_\lambda, \quad (1)$$

where  $\tau_t$  acts on  $t$  by replacing the values of the cells of  $t$ .

Let us define a linear mapping  $\phi : M^\lambda \rightarrow \mathbb{C}[Sym_n]$ . Since the set of all  $\lambda$ -tabloids is a basis for  $M_\lambda$ , it is enough to define images for  $\lambda$ -tabloids. For any  $\lambda$ -tabloid  $\{t\}$ , where  $t \in T_\lambda$ , we put

$$\phi(\{t\}) = \sum_{t' \in \{t\}} \tau_{t'}.$$

# An embedding $\phi$ of $M^\lambda$ into $\mathbb{C}[\text{Sym}_n]$

## Lemma (1)

*For any polytabloid  $\mathbf{e}_t$ , the equality  $\phi(J_n(\mathbf{e}_t)) = J_n(\phi(\mathbf{e}_t))$  holds.*

## Lemma (2)

*Let  $\mathbf{v} \in S^\lambda$  be an eigenfunction of the operator  $J_n : M^\lambda \rightarrow M^\lambda$  with eigenvalue  $\theta$ . Then  $\phi(\mathbf{v})$  is an eigenfunction of the operator  $J_n : \mathbb{C}[\text{Sym}_n] \rightarrow \mathbb{C}[\text{Sym}_n]$  with eigenvalue  $\theta$ .*

## An eigenvector of $J_n$ given by a polytabloid $\mathbf{e}_t$

Let  $\lambda \in \mathcal{P}(n)$  be a partition  $(\lambda_1, \lambda_2, \dots, \lambda_s)$ , where  $s \geq 2$ ,  $\lambda_1 > \lambda_2$  and  $\lambda_i \geq \lambda_{i+1}$  for any  $i \in \{2, \dots, s-1\}$ . Put  $m = \lambda_2 + \dots + \lambda_s$ . In this setting  $m$  is the number of cells in all rows of  $\lambda$  but the first.

Let  $t$  be a standard tableau of shape  $\lambda$  with  $n$  placed at its upper right cell.

### Lemma (3)

*The polytabloid  $\mathbf{e}_t$  is an eigenfunction of  $J_n$  with eigenvalue  $n - m - 1$ .*

# Main result 1: the family of $PI$ -eigenfunctions of $S_n$

Let us take a vector

$$P_m = ((j_1, k_1), (j_2, k_2), \dots, (j_m, k_m))$$

of  $2m$  pairwise different elements from the set  $\{1, \dots, n-1\}$  arranged into  $m$  pairs and a vector

$$I_m = (i_1, i_2, \dots, i_m)$$

of  $m$  pairwise different elements from the set  $\{1, \dots, n\}$ . Define a function  $f_{I_m}^{P_m} : \text{Sym}_n \rightarrow \mathbb{R}$ . For a permutation

$\pi = [\pi_1 \pi_2 \dots \pi_n] \in \text{Sym}_n$ , we put  $f_{I_m}^{P_m}(\pi) = 0$ , if there exists  $t \in \{1, 2, \dots, m\}$  such that  $\pi_{j_t} \neq i_t$  and  $\pi_{k_t} \neq i_t$ . If for every  $t \in \{1, 2, \dots, m\}$  either  $\pi_{j_t} = i_t$  or  $\pi_{k_t} = i_t$ , then we define a binary vector  $X_\pi = (x_1, x_2, \dots, x_m)$  as follows:

$$x_t = \begin{cases} 1, & \text{if } \pi_{j_t} = i_t; \\ 0, & \text{if } \pi_{k_t} = i_t. \end{cases}$$

# Main result 1: the family of $PI$ -eigenfunctions of $S_n$

We use the vector  $X_\pi$  to complete the definition of the function  $f_{I_m}^{P_m}$ :

$$f_{I_m}^{P_m}(\pi) = \begin{cases} 1, & \text{if } X_\pi \text{ contains an even number of 1s;} \\ -1, & \text{if } X_\pi \text{ contains an odd number of 1s;} \\ 0, & \text{there exists } t \text{ such that } \pi_{j_t} \neq i_t \text{ and } \pi_{k_t} \neq i_t. \end{cases}$$

## Theorem (1)

*For  $n \geq 3$ , the function  $f_{I_m}^{P_m}$  is an eigenfunction with eigenvalue  $n - m - 1$  of the Star graph  $S_n$ .*

## Main result 2: an expression of an eigenfunction given by a polytabloid in $PI$ -eigenfunctions

Let  $\mathbf{e}_t$  be an eigenfunction from the Lemma 3, and  $n > 2m$  holds.

For any  $i \in \{1, \dots, s\}$  and  $j \in \{1, \dots, k\}$ , denote by  $R_t(i)$  and  $C_t(j)$  the symmetric groups on the elements of  $i$ th row and  $j$ th column of the tableau  $t$ , respectively. Then we have

$$R_t = R_t(1) \times R_t(2) \times \dots \times R_t(s),$$

$$C_t = C_t(1) \times C_t(2) \times \dots \times C_t(k),$$

where  $R_t$  and  $C_t$  are the row-stabilizer and the column-stabilizer of  $t$ , respectively.

# Main result 2: an expression of an eigenfunction given by a polytabloid in $PI$ -eigenfunctions

Put

$$CA_t = CA_t(1) \times CA_t(2) \times \dots \times CA_t(k),$$

where  $CA_t(j)$  denotes the subgroup of even permutations in  $C_t(j)$ .

## Theorem (2)

*The equality*

$$f_{\phi(\mathbf{e}_t)} = \sum_{\sigma \in R_t(2) \times \dots \times R_t(s)} \sum_{\pi \in CA_{\sigma(t)}} f_{(n-m+1, \dots, n)}^{P_\pi}$$

*holds, where  $P_\pi$  is a vector of  $m$  pairs uniquely determined by  $\pi$ .*

1. Can we construct linearly independent embeddings of a Specht module into  $\mathbb{C}[Sym_n]$ ?
2. Can we write down explicitly a basis of an eigenspace of the Star graph?
3. Is the family of  $PI$ -eigenfunctions complete? It is true in the case of the largest non-principal eigenvalue  $n - 2$  of  $S_n$ . Moreover, we can find a basis among  $PI$ -eigenfunctions.
4. Does there exist an analogue of the  $PI$ -eigenfunctions for the other half of positive eigenvalues of the Star graph?

Thank you for your attention!
